What Does EEG-to-fMRI Synthesis Add to EEG-Based Diagnosis? A Controlled Benchmark in Psychosis, Schizophrenia and Parkinson's Disease

Supplementary tables

Table S1: Added value of synthesized fMRI, full precision. ΔAUC of the combined view over the baseline; 95% and Bonferroni-level (40 comparisons) percentile intervals of a paired stratified bootstrap over subjects (20,000 resamples); two-sided bootstrap p; Holm-adjusted p within the 20 trained-synthesizer comparisons (XP1: within the 20 XP1 comparisons) and within the 40 comparisons including untrained synthesizers.

Baseline	Cohort	Synthesizer	Weights	ΔAUC	95% CI	Bonferroni-40 CI	p	Holm (20)	Holm (40)

Table S2: Sensitivity analyses: AUC of each synthesized view with 20 (primary), 5, 10 or 40 principal components, average pooling in $3 \times 4 \times 4$-voxel blocks, covariates regressed out within training folds, ICA-cleaned inputs (ocular components removed), and synthesizers trained on XP1 (last column; for the last row of each cohort, CNN-TAG trained for 50 epochs). Covariates: age and sex (all cohorts with these data), chlorpromazine-equivalent dose (FEP1, FEP2), recording hour (Semmelweis, Fribourg), recording year (Fribourg).

Table S3: Recording metadata and artefact measures by group: patient and control means, AUC of the measure for the label (Mann–Whitney) and two-sided p; categorical fields with Fisher or χ^2 tests. Artefact measures: fraction of pseudo-TRs exceeding 150 μV peak-to-peak or an EMG-like 30–45 Hz power, median peak-to-peak amplitude (μV), median log 30–45 Hz power, log RMS of the EOG channels and (PD) of the accelerometer, over the analysed crop.
